

Planets by sizes

How do planets sizes compare to each other?

The planets in our solar system are each very unique for various reasons. When it comes to their measurable sizes in diameter, the planets vary greatly. Jupiter, for example, is approximately 11 times the diameter of the Earth. Mercury, on the other hand, is 2.6 times smaller in diameter than the Earth.

How big is Earth compared to other planets?

Earth is basically almost two times bigger than the Red Planet, and it still has more robots, duh! Saturn, which is the second-largest planet in our Solar System, is a monster in comparison to Earth. Saturn has a diameter of approximately 120.536 km / 74.897 mi and a radius of around 58.232 km / 36.183 mi.

What is the largest planet in our solar system?

Earth is the largest terrestrial planet and the only known planet that has life on it. It is the 3rd planet from the sun with a mean distance of around 1 AU. It travels around the sun with a speed of 29.78 km/sec and completes one orbit in 365.24 earth days. The magnetosphere of the earth protects us from harmful solar and cosmic winds.

Here are brief descriptions of the celestial bodies, including planet sizes, in order of distance from the Sun. The Sun. Our solar system's star is classified as a small-to-medium sized star, yet comes in at a whopping 1,329,000 km in diameter and weights approximately 2000 trillion trillion tonnes. That's not a typo, it really is that heavy.

The planets today shows you where the planets are now as a live display - a free online orrery. In this solar system map you can see the planetary positions from 3000 BCE to 3000 CE, and also see when each planet is in retrograde. ... The reason for this is that for one, the constellations vary in size whereas zodiacs are all the same and for ...

Our solar system consists of our star, the Sun, and everything bound to it by gravity - the planets Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus, and Neptune; dwarf planets such as ...

Venus: Similar to Earth in size but with a thick, toxic atmosphere and no moons. Earth: Our home planet with a biosphere and one large moon. Mars: The "Red Planet" with a thin atmosphere, two small moons and the largest volcano in the solar system. Jupiter: The largest planet with colorful cloud bands, a giant storm and over 80 moons.

This is a simple guide to the sizes of planets based on the equatorial diameter - or width - at the equator of each planet. Each planet's width is compared to Earth's equatorial diameter, which is about 7,926 miles (12,756 ...

Planets by sizes

The relative sizes of the planets and the Sun shown on Figure 1 are approximately correct but some other physical properties are imprecise. 1) Distances between planets. The image above shows the planets separated by equal intervals. In reality, of course, those distances are unequal. I could not draw the image with both planet sizes and ...

Size and Distance. Size and Distance. Our solar system extends much farther than the eight planets that orbit the Sun. The solar system also includes the Kuiper Belt that lies past Neptune's orbit. This is a sparsely occupied ring of icy bodies, almost all smaller than the most popular Kuiper Belt Object - dwarf planet Pluto.

The sizes of the planets vary greatly as do the distances between planets and their distance from the Sun. The size of the Sun at larger scale (which isn't included in printouts) would have been 76.7 inches (195 centimeters) in diameter (38.4 inches in radius).

The Earth is actually one of the smaller planets compared to the giant planets in the outer solar system - Jupiter, Saturn, Uranus, and Neptune. The table below lists the diameters of the planets and the Sun compared to the Earth. Body Diameter (Earth = 1) Sun: 109: Mercury.38: Venus.95: Earth: 1: Mars.53: Jupiter: 11.19: Saturn: 9.40: Uranus ...

The planets in our solar system are each very unique for various reasons. When it comes to their measurable sizes in diameter, the planets vary greatly. Jupiter, for example, is approximately 11 times the diameter of the Earth. Mercury, on the other hand, is 2.6 times smaller in diameter than the Earth. Below you will [...]

This activity explores the relative size of these eight planets. Is one bigger than the others, or are they all about the same size? This activity is not recommended for use as a science fair project. Good science fair projects have a stronger focus on controlling variables, taking accurate measurements, and analyzing data.

The four large outer worlds -- Jupiter, Saturn, Uranus and Neptune -- are sometimes called the Jovian or "Jupiter-like" planets because of their enormous size relative to the terrestrial planets ...

While a planet travels in one direction, it is also affected by the Sun's gravity causing it to take a curved route that eventually brings it back to its starting point. ... Previous Post: Pluto Size, Composition, Distance from Sun & Moons. Next Post: The Planets and Moons of Star Wars to Scale. Related space facts: 81 comments Coolster says ...

The other planets are shared the residue of the gravitational evolution, i.e. 0.038% of the total mass. The four terrestrial planets represent only 11.17% of the total mass of the solar system planets. Image: Comparative sizes of 4 terrestrial planets, Mercury left, Venus, Earth and Mars.

5 days ago· solar system to scale The eight planets of the solar system and Pluto, in a montage of images scaled to show the approximate sizes of the bodies relative to one another. Outward from the Sun, which is represented to scale by the yellow segment at the extreme left, are the four rocky terrestrial planets

(Mercury, Venus, Earth, and Mars), the ...

The order of the planets from the Sun, starting closest and moving outwards: Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus, Neptune. Skip to content. Blog; Equipment. Star Trackers; ... It is similar to Earth in size and mass and ...

An overview of the history, mythology and current scientific knowledge of the planets, moons and other objects in our solar system. Skip to content. Menu. The Nine Planets ... Jupiter is a massive planet, twice the size of all other planets combined, and ...

For each planet, look up how far the planet's label needs to be from the thumbtack in your model; it is listed in the "Model Distance" column. Then, repeat step 2 marking a point at the distance you just looked up. For example, for the ...

Calculating the size of Earth's entire surface area provides an interesting picture of just how much of our planet is covered by ocean versus land. To find the total surface area, we need to use the average radius of Earth - approximately 3,959 miles - and plug it into the standard formula for the surface area of a sphere.

For each planet, look up how far the planet's label needs to be from the thumbtack in your model; it is listed in the "Model Distance" column. Then, repeat step 2 marking a point at the distance you just looked up. For example, for the planet Mars, mark a point 15 cm from the label as you want Mars to be 15 cm from the Sun in your model.

A solar eruption captured by SOHO (Solar and Heliospheric Observatory). The Earth is shown here for size comparison. Image credit: SOHO (ESA & NASA) Distances. There are four rocky planets and four giant planets in our solar system. The distance between the planets is large, particularly for the giant planets in our outer solar system.

For example, if you order the planets by size (radius) from biggest to smallest, then the list would be: Advertisement. The Planets in Order by Size. Jupiter (43,441 miles/69,911 kilometers) Saturn (36,184 miles/58,232 km) Uranus (15,759 miles (25,362 km) Neptune (15,299 miles/24,622 km)
